

CHAPTER 4 CONTENT ERROR

Content error has been estimated only for matched persons and for selected variables. One of the objectives of the Post Enumeration Survey (PES) is an assessment of the quality of the particulars recorded in the census for the individuals who were enumerated. The following questions were canvassed in the PES for assessing the quality of the particulars collected in census.

1. Name of the person
2. Relationship to the head
3. Sex
4. Age last birthday
5. Current marital status
6. Literacy status
7. Highest educational level attained
8. Type of disability
9. Characteristics of workers and non-workers
10. Economic activity of the main or marginal workers and
11. Fertility particulars

4.2 Detailed instructions issued to fill up the Schedule VI are given in Appendix I.

4.3 The data collection for assessing the extent of content error in census was done through Schedule VI. This was canvassed in a 20 percent sub-sample of the selected EBs for estimating the coverage error. So, if the EB in which the Schedules I and IV were canvassed is included in the sub-sample, then Schedule VI was also canvassed immediately after canvassing the Schedules I and IV. The desk matching and the field reconciliation visit were also done simultaneously along with those of Schedules I and IV. The indices of *response bias* and *response variance* were estimated based on the data collected and the methodology followed were the same as in 1991 Detailed results for coverage errors are presented in Tables 4.1-4.10. The methodology followed is described in the following paragraphs: -

4.4 The *response bias* of a statistic for an area is that part of the response error, which would not tend to average out over the work of many interviewers who might be assigned to the area or the many conceivable responses of the respondents in the area. It may and often will differ between types of areas or between one survey or one census and the next, although it may tend to be consistent in direction and to a considerable degree in amount.

4.5 The *response variance* of a statistic arises from factors that would tend to average out through compensating errors in a large number of repetitions of the experience, but that may in a particular limited set of measurements have a significant effect on the accuracy of the result. For example, census figures for very small areas or for very detailed tabulation cells for large areas may be much more significantly affected by enumerator's errors, than will be summary figures for large areas such as state or national figures. The enumeration in a particular tabulation area may reflect the work of only a few enumerators. Each enumerator may introduce certain types of more or less

consistent or correlated errors within his work. Such errors generally may tend to balance out over a large number of enumerators but may have a substantial effect on the statistics for small areas or small tabulation cells. The differences in performance among enumerators are in many cases an important component of response variance. This is particularly important in the census, as data collection is completely in the hands of enumerators.

4.6 Six indices have been estimated to measure response bias and response variance, two relating to response bias and the other three to response variance. These indices are as below: -

Indices of Response bias:

- (i) Net Difference Rate
- (ii) Net Shift Rate

Response variance:

- (i) Gross Difference Rate
- (ii) Index of Inconsistency
- (iii) Aggregate Index of Inconsistency
- (iv) Proportion of Standard Differently Reported

4.7 The significance of response bias and variance can be explained, by way of an example, with reference to the work category. In the PES it was determined whether a person was a worker or not based on the fact whether he worked any time at all during last year. The PES results relating to this characteristic can be compared with those of the Census in relation to the same characteristic and the classificatory differences can be considered on the following basis: -

Classification of workers and non-workers in PES and Census

PES as	Number of persons classified in		
	Census as		
	Worker	Non worker	Total
Worker	a	b	a+ b
Non-worker	c	d	c+ d
Total	a+ c	b+ d	n=a +b +c +d

b and c, in this example represent the classificatory difference between the PES and the Census. The indices of response bias and response variance referred to above have been developed on this basis and are explained further.

Net Difference Rate (NDR)

4.8 If PES is regarded as an improvement over the census and as standard by which to judge the census results then the difference between the two sets of worker figures ($a + b$) and ($a + c$) is net difference. The Net Difference Rate (NDR) is calculated as follows:

$$NDR = \frac{(a+c)-(a+b)}{n} \times 100 = \frac{c-b}{n} \times 100$$

4.9 If the sign of this index is positive it would mean that a larger number of persons have been classified as workers in the census than is really the case. If the sign is negative, it would mean that there has been an under estimation of workers in the census.

Net Shift Rate (NSR)

4.10 This shows the net difference as a percentage of persons classified in PES in a group. While in net difference rate the total population 'n' is the denominator, in net shift rate, the number of persons classified in PES as in a group (i.e., a +b) forms the denominator. The formula for index of net shift is

$$NSR = \frac{(a+c)-(a+b)}{a+b} \times 100 = \frac{c-b}{a+b} \times 100$$

Gross Difference Rate (g)

4.11 It is the percentage of the persons for whom the classification differs in the census and PES, i.e.

$$g = \frac{b+c}{n} \times 100$$

4.12 $g/2$ is an estimate of simple response variance 'g' is an extremely useful index. It provides a useful measure of the consistency or reliability of measurement process. If both the PES and census enumerators classify a person in the same manner then 'g' will be zero. Values of g farther away from 'zero' indicate that the measurement of the characteristic is less reliable.

Index of Inconsistency (I)

4.13 $p = \frac{(a+c)}{n}$ will be the proportion of persons classified as 'worker' in census. The variance of this proportion is $p(1-p)$. The ratio of simple response variance $g/2$ to the variance $p(1-p)$ is defined as the *Index of Inconsistency*.

$$I = \frac{g}{2} \div p(1-p)$$

The farther the value of I from zero, the less reliable is the measurement of the characteristic.

Proportion of Standard differently report \hat{r}

4.14 This is the proportion of cases in PES, which were differently reported in census.

Symbolically, $\hat{r} = b/(a + b)$ this provides an index of the stability of the response relative to the standard. This gives an idea of the proportion PES group that was differently classified in census and the proportion that was identically classified.

4.15 The Statement 1 given below illustrates the Gross Difference Rate, Agreement Rate and Aggregate Index of Inconsistency based on the results of the PES on the quality of the particulars recorded in the census. Gross Difference Rate (GDR), the measure of response, is the percentage of classification difference between the estimator and the parameter under study. Agreement Rate is the compliment of GDR. A low rate of agreement indicates a high degree of variability and vise-versa. Aggregate Index of Inconsistency is the relative number of cases, the categories of the characteristic taken as a whole, for which the response varied between the census and the PES. If the Aggregate Index of Inconsistency is less than 20, the response variance is considered low (L), if it falls between 20 and 50 the index is Moderate (M) and if it is grater than 50 the index is High (H). Irrespective of the residence, the GDR for the persons enumerated is negligible and there is a two percent difference in case of relationship to the head of the family. Only 83 percent of responses were the same in both PES and census. In all other characteristics, the GDR seems to be insignificant, or in other words, the agreement rates are almost the same in both PES and census. The response variance is low for all the characteristics under study.

STATEMENT 1
GROSS DIFFERENCE RATE, AGREEMENT RATE AND AGGREGATE INDEX OF INCONSISTENCY - INDIA

neg- negligible

4.16 Net Difference Rate (NDR) and the Index of Inconsistency for persons enumerated by age groups and residence are given in Statement 2. Irrespective of the location, the NDRs are negative in the age groups 5-9, 15-19, 20-24, 25-29, 30-34 showing under estimation in census. The under estimation is found in PES in the age group of 60+. The measure of index of inconsistency is low up to the age groups 20-24 and moderate in all other age groups. These results show the effect of response errors on age distributions, which has also been analysed in the 'Report and Tables on Age', Census of India 2001

STATEMENT - 2
NET DIFFERENCE RATE AND INDEX OF INCONSISTENCY FOR PERSONS
ENUMERATED BY AGE AND RESIDENCE - INDIA

Age-groups	Net Difference Rate %			Index of Inconsistency		
	Total	Rural	Urban	Total	Rural	Urban

55-59	neg	neg	neg	M	M	M
60+	0.9	0.8	1.1	M	M	M

Note: -

Index of inconsistency less than 20, L-Low

Index of inconsistency between 20 and 50, M-Moderate

Index of inconsistency greater than 50, H-High

neg- negligible

4.17 The Statement 3 presents the Net Difference Rate and Index of Inconsistency for persons enumerated by marital status and residence. While the NDRs are negative in case of males, it is positive in case of females. This shows that, there is an equal amount of misclassification in identifying the marital status category among the sex. The measure of index of inconsistency is low in each category and in each location. This indicates the errors of classification could not affect conclusions drawn from the data

STATEMENT - 3

neg- negligible

4.18 Net Difference Rate and Index of Inconsistency for persons enumerated by educational levels, literacy status and residence are given below in Statement 4. There does not exist any significant variation in the category of educational levels and also in the literacy status. The NDRs show under estimation in census in these categories. Only literate without educational level in urban area and unclassified educational attainment in rural area has moderate measure of index of inconsistency and all others have been categorised as low.

STATEMENT - 4
NET DIFFERENCE RATE AND INDEX OF INCONSISTENCY FOR PERSONS ENUMERATED
BY EDUCATIONAL LEVELS, LITERACY STATUS AND RESIDENCE - INDIA
